CLAIMS

What is claimed is:

1	 A method for responding to a request to transfer data between a virtual
2	machine (VM) in a virtual computer system and a data storage unit within a multipath
3	data storage system, the method comprising:
4	determining multipath routing information related to possible paths over
5	which the data may be routed;
6	determining VM-specific information related to the VM in the virtual
7	computer system;
8	based on the multipath routing information and the VM-specific
9	information, deciding whether to route the data transfer request; and
10	if a decision is made to route the data transfer request, then, based on the
11	multipath routing information and the VM-specific information, selecting a path
12	over which to route the data.

- 2. The method of claim 1, in which the VM-specific information indicates an amount of disk bandwidth that is allocated to the VM.
- 3. The method of claim 2, in which a decision is made not to route the data transfer request because routing the data transfer request would cause the VM's allocation of disk bandwidth to be exceeded.
- 4. The method of claim 1, in which the VM-specific information indicates the VM's priority relative to other virtual machines.
- 5. The method of claim 1, in which the multipath routing information indicates the available paths over which the data may be routed.

1 6. The method of claim 5, in which the multipath routing information further indicates a pending data transfer load for each of the available paths over which the data may be routed.

- 7. The method of claim 1, in which a load distribution function, based on the multipath routing information and the VM-specific information, is used in selecting a path over which to route the data.
 - 8. The method of claim 7, in which a first VM's data transfer requests are substantially always routed over a first data path as long as the first data path is available, and a second VM's data transfer requests are substantially always routed over a second data path as long as the second data path is available.
- 9. The method of claim 1, in which the multipath routing information indicates whether a failover is occurring on one of the paths over which the data could otherwise have been routed.
- 1 10. The method of claim 9, in which the VM is temporarily suspended if a 2 failover is occurring on one of the paths over which the data could otherwise have been 3 routed.
- 1 11. The method of claim 1, wherein, if a decision is made not to route the data 2 transfer request, the data transfer request is placed on a queue for routing at a later 3 time.
- 1 12. The method of claim 1, wherein, if a decision is made not to route the data 2 transfer request, a further decision is made whether to suspend the VM.
 - 13. The method of claim 1, wherein, if a decision is made not to route the data transfer request, a further decision is made whether to migrate the VM to another computer system.

1 14. A computer program embodied in a tangible medium, the computer
2 program executing in a virtual computer system in support of a plurality of VMs, the
3 virtual computer system having access to a multipath data storage system, the
4 computer program comprising:
5 a resource manager for sharing system resources between the plurality of
6 VMs; and

1 2

a storage path manager for routing data between the plurality of VMs and the data storage system, over the multiple data paths,

wherein the computer program determines VM-specific information and multipath routing information and the storage path manager makes multipath routing decisions based on both the VM-specific information and the multipath routing information.

- 15. The computer program of claim 14, wherein the VM-specific information and the multipath routing information are used together when making decisions regarding the sharing of system resources.
- 16. The computer program of claim 15, wherein the decisions regarding the sharing of system resources are based on a proportional-share approach.
- 17. The computer program of claim 14, further comprising a VM manager for controlling the general operation of the plurality of VMs.
- 18. The computer program of claim 17, wherein the VM-specific information and the multipath routing information are used together when making decisions regarding the management of the plurality of VMs.
- 19. The computer program of claim 17, wherein the VM manager and the resource manager are both implemented in a single software unit.

1 20. The computer program of claim 17, wherein the VM manager, the 2 resource manager and the storage path manager are integrated together within a 3 kernel.

- 1 21. The computer program of claim 17, further comprising a storage virtualizer 2 for presenting one or more portions of the data storage system to one or more of the 3 VMs as one or more virtual disk drives.
- 22. A method for selecting a path to be used for a data transfer between a VM within a virtual computer system and a storage unit within a multipath data storage system, the virtual computer system comprising a plurality of VMs, the method comprising:

1

determining which VM within the virtual computer system is involved in the data transfer;

determining a plurality of available paths over which the data may be routed; and

based on the particular VM involved in the data transfer and the available paths over which the data may be routed, selecting a path over which to route the data.

- 23. The method of claim 22, wherein the selection of a path over which to route the data is further based on information regarding pending data loads on the available paths over which the data may be routed.
- 24. The method of claim 22, wherein the selection of a path over which to route the data is further based on relative priorities for the plurality of VMs.
- 25. The method of claim 22, wherein the selection of a path over which to route the data is further based on system resource allocations for the plurality of VMs.

- 26. The method of claim 22, wherein the selection of a path over which to route the data is based on a load distribution algorithm.
- 27. The method of claim 26, wherein the load distribution algorithm is a load balancing algorithm.
- 28. A method for routing data between a virtual computer system and a multipath data storage system, the virtual computer system comprising a first VM and a second VM, the multipath data storage system comprising a first data path and a second data path between the virtual computer system and one or more data storage units, the method comprising:

for each data transfer request:

1 2

determining which VM within the virtual computer system is involved in the requested data transfer; and

if the first VM is involved in the requested data transfer, routing the data over the first data path; or

if the second VM is involved in the requested data transfer, routing the data over the second data path.

- 29. The method of claim 28, in which the one or more data storage units are connected directly to the virtual computer system.
- 30. The method of claim 28, in which the one or more data storage units are connected to the virtual computer system through a network.
 - 31. The method of claim 30, in which the network is a storage area network.
